A6 AMMO STATS

A desktop app to load your Ammo.pbo and WeaponScripts.pbo, edit real ammo/damage values through a simple form, and pack the result straight back into a .pbo.

01 What is A6 Ammo Stats?

A6 Ammo Stats is a standalone desktop tool for editing the real in-game stats of every A6 ammo caliber — damage, velocity, deflection, noise, and more — without touching a text editor or a hex editor.

You load your own `Ammo.pbo` and `WeaponScripts.pbo`, the app reads every real caliber's config out of them (currently 20 real calibers from the base A6 pack), lets you edit any stat through plain number fields, and packs your changes back into a new `.pbo` you can drop straight onto your server.

NOTHING IS GUESSED

Every field in this app maps to a real, named value inside the actual game config — the same `cfgAmmo` data the DayZ engine itself reads. There is no invented or approximated stat anywhere in this tool.

What it does not do

It does not sign your packed `.pbo` — you sign it yourself with your own key, the same way you always do. It also does not touch weapon-side stats (recoil, sway, fire rate) — only the ammo/damage side.

02 Installing the app

- 1 Run `A6 Ammo Stats Setup 1.0.0.exe`.
- 2 The installer will ask where to install — pick any folder, or keep the default.
- 3 Click through to finish. No other setup, no extra downloads.
- 4 Launch **A6 Ammo Stats** from your Start Menu or Desktop shortcut.

ONE REAL LIMITATION

If the pbo you load stores its config in *binarized* form (`config.bin` — true for the stock A6 `Ammo.pbo` / `WeaponScripts.pbo`), converting that to readable text currently needs

DAYZ TOOLS

installed on the same machine (free, via Steam). This only affects the *loading* step — packing your edited result back out never needs DayZ Tools. If DayZ Tools isn't found, the app tells you clearly instead of failing silently.

03 Loading your files

On first launch, the app is empty — nothing to edit until you point it at your files.

The app on first launch. Two buttons, nothing loaded yet.

- 1 Click **Load Ammo.pbo** and pick your `Ammo.pbo` file.
- 2 Click **Load WeaponScripts.pbo** and pick your `WeaponScripts.pbo` file.
- 3 The app unpacks both, converts any binarized configs to text, and reads every real caliber it finds — this takes a few seconds.

You don't have to load both at once — loading just one still works, you'll just see fewer calibers (whichever file actually contains the caliber's `cfgAmmo` data).

Both files loaded — both buttons show a checkmark, and the left sidebar fills with every real caliber found (20, for the stock A6 pack).

04 Browsing & searching calibers

The left sidebar lists every caliber the app found, sorted alphabetically. Each row shows the caliber name and its real in-game classname underneath (e.g. `Bullet_A6_127x99`) — useful for confirming you're editing the exact round you think you are.

Click any row to open it in the editor. Type in the search box at the top of the sidebar to filter by caliber name or classname as you type.

Typing "50" narrows the list to only the .50-family calibers. Search matches both the caliber name and the classname.

05 The Ballistics fields, explained

Selecting a caliber opens its full stat sheet. The top group, **Ballistics**, controls how the round behaves in flight and what it does to hard surfaces.

12.7x99 selected, unmodified — every field pre-filled with the round's real current value.

FIELD	WHAT IT CONTROLS
Hit (Damage)	The base direct-hit damage this round deals on a solid hit, before any hit-zone or armor multipliers apply. This is the single biggest lever for "how deadly is this round."
Indirect Hit	Splash/area damage dealt to targets <i>near</i> the impact point rather than directly hit. <code>0</code> for a normal bullet — only meaningful for explosive-type rounds.
Indirect Range	The radius, in meters, that Indirect Hit reaches. Has no effect while Indirect Hit is <code>0</code> .
Init Speed (m/s)	Muzzle velocity — how fast the round leaves the barrel. Higher means flatter trajectory and less drop over distance.
Typical Speed	A reference velocity the engine uses for its own ballistic/sound-timing math. On real A6 rounds this normally matches Init Speed exactly.
Caliber	An abstracted game value (not the literal mm bore size) that governs how well this round penetrates cover and armor. A 12.7x99 round shows <code>3.5</code> here, not <code>12.7</code> — don't confuse it with the real-world caliber in the round's name.
Deflecting	How prone the round is to ricochet off hard/angled surfaces instead of penetrating.

Air Friction	Always a small negative number — controls how quickly the round loses velocity over distance. More negative means faster drop-off at range.
Barrel Wear	How much firing this round wears down the weapon's barrel condition per shot.
Round Weight	The individual cartridge's weight — feeds into the loaded magazine's total inventory weight.

06 The Damage fields, explained

The second group, **Damage**, controls exactly what happens to a player's health when this round hits them.

FIELD	WHAT IT CONTROLS
Health Damage	Direct damage applied to the player's overall health pool on a hit.
Armor Damage	Damage applied specifically to worn armor/plate durability when the hit lands on an armored zone.
Blood Damage	Damage applied to the player's blood level — drives bleeding severity.
Shock Damage	Damage applied to the shock system, tied to pain/incapacitation response.
Noise Strength	How loud this shot registers to nearby AI and players for detection purposes.

Below the Damage group, a read-only **Magazine** panel shows the real loaded-magazine item this round belongs to (its display name, classname, weight, and round count) — for reference only, not editable here.

07 Editing a value

Click into any field and type a new number. That's it — no save button per field, no confirmation dialog.

- 1 Click the field you want to change.
- 2 Type the new value.
- 3 The field's border turns amber, and a **MODIFIED** badge appears next to the caliber name.

Hit (Damage) changed from 17 to 22 on 12.7x99 — the field is amber-highlighted, the MODIFIED badge is showing, and the change is already listed on the right.

CHANGES ARE PER-CALIBER, NOT GLOBAL

Editing one caliber never affects any other — every caliber's edits are tracked completely independently, so you can safely tune several rounds in one sitting before packing.

08 Reviewing pending changes

The right-hand **Pending Changes** panel is your running summary of everything you've edited since loading — across every caliber, not just the one currently open. Each entry shows the exact field, its original value, and your new value.

Three calibers edited in one session — 12.7x99, 50AE, and 556x45 — each with its own change listed. Notice the small ● dot next to a caliber's name in the sidebar: that's how you can tell at a glance which calibers you've touched.

Typing a value back to its original number automatically removes it from this list — there's no separate "undo" needed, just retype the original.

09 Packing your changes back into a .pbo

Once you're happy with your edits, use the two buttons at the bottom of the Pending Changes panel:

- 1 **Pack Ammo.pbo** — writes every pending change back into the Ammo.pbo you loaded, and packs a new `.pbo`.
- 2 **Pack WeaponScripts.pbo** — same, for WeaponScripts.pbo. Since the real A6 ammo data lives in WeaponScripts.pbo, this is normally the one you want.
- 3 A save dialog opens — pick where to save the new file and what to name it.
- 4 The app writes your edits into the real config text (only the exact fields you changed — everything else in the file stays byte-for-byte identical) and packs it into the new pbo.

SIGNING IS UP TO YOU

The packed pbo is intentionally left unsigned — sign it yourself with your own key before deploying it, exactly like any other pbo you build.

10 Troubleshooting & known limitations

"...needs DayZ Tools to be installed"

You'll see this if the pbo you loaded has binarized configs and DayZ Tools isn't installed on this machine. Install DayZ Tools via Steam (it's free) and try loading again.

A caliber I expected isn't in the list

Only calibers with a real `cfgAmmo` entry show up. A handful of files in the base pack (like `VanillaAdaptations`) intentionally patch vanilla weapon configs instead of defining a new ammo type, so they contribute no caliber to the list — that's expected, not a bug.

My typing didn't seem to register

Click directly into the field first (a single click is enough), then type. If a field ever seems to ignore input, closing and reopening the caliber (click it again in the sidebar) resets the view without losing any already-tracked changes.

11 Quick reference

ACTION	HOW
Load a file	Top bar → Load Ammo.pbo / Load WeaponScripts.pbo
Find a caliber	Type into the search box above the caliber list
Edit a stat	Click the field, type a new number
See what's changed	Right panel, "Pending Changes" — every caliber, every field
Revert one field	Retype its original value
Save your work	Pack Ammo.pbo / Pack WeaponScripts.pbo → choose a save location

That's the whole workflow — load, browse, edit, review, pack. Everything you see in this app reads and writes the real config data your server actually runs.
